Hypothesis: Determine if the survival rate is associated to the age of passenger

Data Description:

Age – For this analysis, the ages of the passengers are grouped into 3 categories namely:

Children – 0 to 19 years {164}

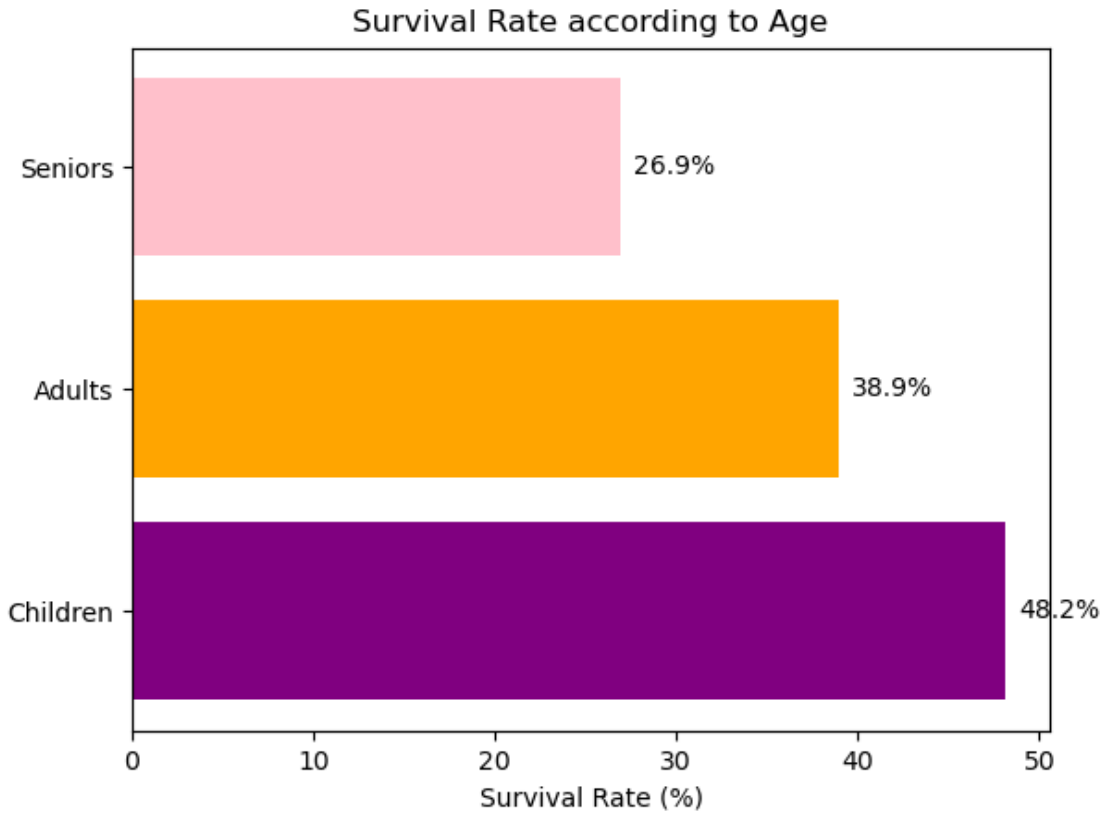

Adults – 20 to 59 years {524}

Seniors – 60+ years {28}

Analysis:

The titanic dataset has 891 records of the 891 records; 716 passengers ages are accounted for. There are 164 children aged between 0 years and 19 years, 524 adults, between 20 – 59 years old, and finally seniors who accounted for passengers north of 60 years old.

Of the 164 children in the dataset, 79 survived. Of the 524 adults, 204 survived while the seniors had 7 survivors out of the 26 0n board. The numbers reflect approximately 48%, 38% and 26% survival rates respectively.

According to the bar graph, the rate of survival in children was significantly higher than any of the other two age groups.

This might have been because of the children – *and women* being evacuated first.

*According to reports, women and children were evacuated first after disaster struck.

**"At about 12.30 the order was given to place women and children in the boats."*
