Hypothesis: Determine if the survival rate is associated to the class of passenger

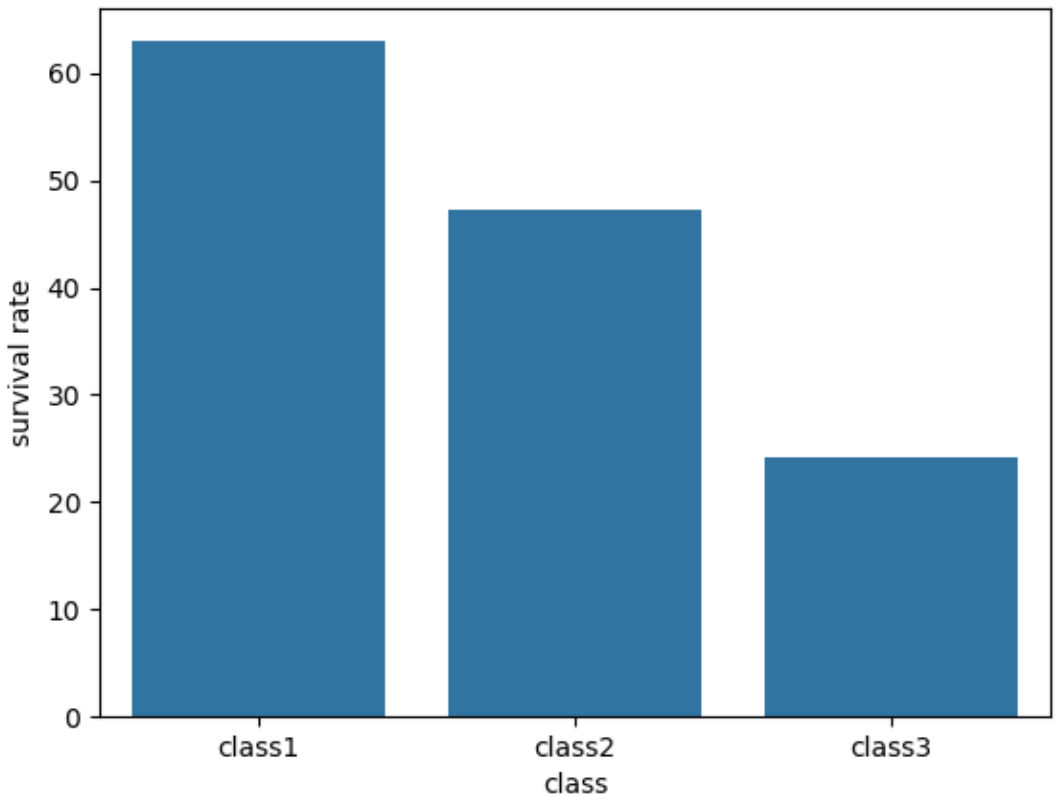

Analysis:

The Titanic had three classes of passenger tickets; classes 1, 2 and 3.

Class 1 was the most expensive passenger class, followed by class 2, and then class 3, which was the cheapest passenger class.

The classes were grouped according to the price of the tickets. Class 1 being the most expensive ticket, followed by class 2 and then class 3 was the least expensive.

Below is a graph that shows the rate of survival for each of the classes.

The survival rate for each class was determined by the **total number of passengers who survived** in each class **divided by** the **total number of passengers** in each class.

According to the graph, about 62% of the passengers with a class 1 ticket survived the wreck, while passengers with classes 2 and 3 accounted for approximately 47% and 24% of survivors respectively.

Therefore, from the analysis, one can say that the higher the class, the higher the passenger’s chance of survival.
