Hypothesis: Determine if the survival rate is associated to the gender of passenger

Analysis:

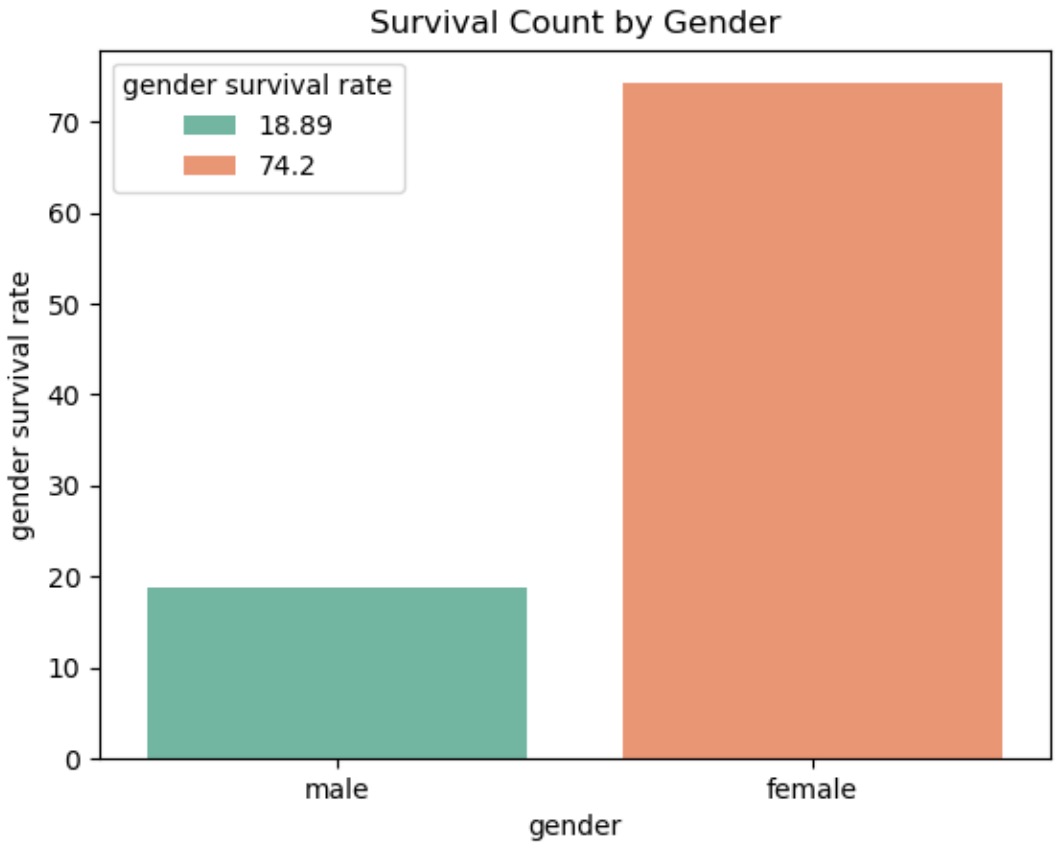

The RMS Titanic dataset has two classes of gender in the dataset; 'male' and 'female'.

The male gender makes up a total of 577 passengers while the female gender makes up 314 passengers.

Of the 577 men in the dataset, 109 of them survived which brings the survival rate in men to approximately 18%.

314 women aboard the RMS Titanic (according to the dataset) and 233 of them survived which accounts for approximately 74% survival rate in women.

Below is a graph that shows this statistic

Conclusion: The gender of the passenger may have had a significant association to whether the passenger survived or not.

*According to reports, women and children were evacuated first after disaster struck.

**"At about 12.30 the order was given to place women and children in the boats."*
